1. **Which player characteristics predict injury, and does the effect of training load depend on age?**

We selected this question because understanding the factors associated with player injuries could provide useful information for Ashford United FC when considering player availability and management. The question is particularly suitable for this project because the league_players.csv dataset contains information on 620 players, including injury status, age, training load, previous injuries, BMI, minutes played and playing position. This allows us to investigate several potential explanatory variables and explore their relationships with injury likelihood.

As injury is recorded as either injured or not injured, logistic regression is a suitable model for this analysis. Furthermore, investigating an interaction between age and training load allows us to explore whether the association between training load and injury varies across different ages, rather than assuming that the relationship is the same for all players.

The question therefore provides opportunities for exploratory data analysis, model selection, comparison of competing models, diagnostic assessment and interpretation of results with appropriate uncertainty. We believe it is both relevant to the club and sufficiently complex to demonstrate the analytical skills expected in this project.
